

MANAGEMENT

Perform more public outreach and education.

- Promote public awareness of water issues and recognition of true value of water-cost will only rise.
- Social media is becoming an important communication tool and a means of knowledge transfer.
- Promote conservation (using less water, etc.).

- Plan for systems sustainability and resiliency.
- Water professionals need to be more aware of production of greenhouse gases from various treatment processes.
- Promote energy efficiency and plant optimization.
- Consider gray water systems.
- Consider reclaimed water-direct and indirect water reuse.
- Manage nonpoint source pollution.

- Manage limited business resources—do more with less. Systems are growing, but budgets are not.
- Provide adequate human resources.
- Retain employees.
- Target research and emphasize regional differences as to water/wastewater needs.
 - Nutrients management is a coastal concern; not so much of a problem in the middle of the country.
 - Majority of water plants are small many size differentials, based on region.
- Systems have historically been decentralized, then became large and centralized. Now they're heading back to being more decentralized.
 - Centralized facilities tend to be used for economy of scale, but the trend is now moving back in the opposite direction.
- Decentralization promotes reclamation and reuse (i.e., reclaim and reuse water at the point of generation).
- Build durability in systems for emergency response, including preparedness for extreme weather and other natural and human-made disasters.
- Address homeland security issues (e.g., training for human-made disasters and emergencies).
- Identify and recover operation maintenance cost between new development and users (full cost recovery).
- Determine how to pay for needed infrastructure.
- Prepare for pollutant credit trading programs.
- Manage distribution and collection for system optimization.
- Utilize asset management systems.
- Perform succession planning.
- Legislation, rules, and regulations are changing more rapidly than ever, and this will likely increase.
- Simplify overly-complicated regulatory reporting requirements.

Emerging Issues & Future Trends

How can high schools & community colleges contribute to the Water Management field?

High school and community college guidance counselors and advisors can convey to potential students what a valuable and important line of work Water Management can be. Not many people initially consider the water field, but it's a great and relatively stable career path. Additionally, it's largely immune to external anomalies and cannot be exported outside the U.S.

Technology

- Green infrastructure
- Sustainable and resilient systems
- Energy recovery
- Nutrient recovery
- Desalinization
- Resources reuse
- Integration of renewable energy into facilities (energy recovery, etc.)
- Quality assurance technology
- Management of microconstituents
- Increased use of computer controls for treatment processes
- Advances in analyzing
- Zero discharge technologies
- AMR (Automated Meter Reading)
- Global access to safe drinking water (wells, purification, etc).

Training

- Funding
- Distance training
- Encourage operators to become trainers, to utilize experienced operators' knowledge in training.
- Standardize the requirements for Continuing Education Units (CEUs) and contact hours across the country (currently developed state by state).
- Mandatory certification for wastewater
- Stormwater certification
- Promote knowledge transfer and ability to operate facility in a manual mode during an emergency and/or disaster.
- Leadership development
